The main difference between a CT Scan and an MRI is the way the two scanning devices work. The CT scan uses x-rays to scan the body and to capture pictures in the details. CT Scan exposes one to forms of radiation. The CT machines have become faster over time thus the patient is exposed to a lower level of radiation today.

Difference Between CT Scan and MRI of Brain - HRF

A Brief Overview of How CT and MRI Works. For both CT (left) and MRI (right) scans you will lie on a moving table and be put into a circular machine that looks like a big doughnut. The table will move your body into the doughnut hole. The scan will then be performed. You may or may not get IV contrast through an IV.

This review focuses on the role of CT and MRI in the diagnosis, follow-up, and surgical planning of aortic aneurysms and acute aortic syndromes, including aortic dissection, intramural hematoma, and penetrating aortic ulcer. It also provides a systematic approach to the definition, causes, natural history, and imaging principles of these diseases.

CT is much faster than MRI, making it the study of choice in cases of trauma and other acute neurological emergencies. CT can be obtained at considerably less cost than MRI, and is sufficient to exclude many neurological disorders. CT is less sensitive to patient motion during the examination, because the imaging can be performed much more rapidly.

The typical imaging features of adenoma have been described in the previous CT and MRI sections and include the following: small size (usually < 4 cm), homogeneous and well-circumscribed, presence of intracellular lipid, low to intermediate signal intensity on T2-weighted images, and washout of contrast material on CT studies performed using a dedicated multiphase adrenal CT protocol.

CT scans utilize X-rays to produce images of the inside of the body while MRI (magnetic resonance imaging) uses powerful magnetic fields and radio frequency pulses to produce detailed pictures of organs and other internal body structures. CT scans use radiation (X-rays), and MRIs do not. MRIs provide more detailed information about the inner organs (soft tissues) such as the brain, skeletal system, reproductive system and other organ systems than is provided by a CT scan.

An MRI differs from a CAT scan (also called a CT scan or a computed axial tomography scan) because it does not use radiation. MRI scans are better for imaging water-containing tissue. An MRI can be better at detecting abnormalities of the spinal cord, bulging discs, small disc herniation's, pinched nerves and other soft tissue problems.
