Abstract. A practical rolling resistance simulation method for tires using a static finite element method is presented that fulfills three requirements: (1) easy input data preparation, (2) shorter computation time, and (3) adequate accuracy. The method implements a static deflection analysis first and the stress and strain thus obtained, together with the loss factors of the materials determined separately, are used to estimate the energy dissipation of a rolling tire.

Also modeling how rolling radius change with respect to load and speed is now necessary to complement aerodynamics calculations and required some further input, so the tire tab is now pretty busy! Suspension kinematics files include, as we have seen already, how camber change with respect to wheel travel and steering angle.
